High Strain-Rate Superplasticity (HSRS) is extremely rare in high strength materials, and the lack of superplastic forming capability in a recently emerged class of high-strength materials, the so-called High-Entropy Alloys (HEAs), is a serious obstacle for its potential use in engineering complex structures. HEAs have a unique alloy design concept based on multi-principle elements, and they exhibit remarkable properties such as high strength combined with high ductility as well as high fracture toughness when compared to conventional alloys \cite{1}. Thus, achieving HSRS in HEAs would signify a huge breakthrough in advanced material science. In this presentation, we present a superplastic elongation to 2,000% of the original length at a high strain rate of 5x10\textsuperscript{-2} s\textsuperscript{-1} in an Al\textsubscript{9}(CoCrFeMnNi)\textsubscript{91} (at\%) high-entropy alloy nanostructured using high-pressure torsion. The high-pressure torsion-induced grain refinement in the multi-phase alloy combined with limited grain growth during hot plastic deformation enables high strain rate superplasticity through grain boundary sliding accommodated by dislocation activity \cite{2,3}.
